# 1 Getting Started

This section introduces the basics of C++ programming language and the tools needed to follow this tutorial. The goal of this tutorial is to help beginners getting started with C++ programming language. It does not require you to have a prior programming background knowledge. All you have to do is to follow along with me and try to **WRITE** the code on your own machine not just read. Believe me it is easier to read and assume that you have mastered it until you are required to write the code by yourself, that is where it realize you have not properly understood it.

## 1.1 Understand the Computer Language

Your computer is an incredible and complicated device. Basically, the computer understands one simple language composed of 0 and 1. Thus a message like this "01001100101001010" could mean "open a window" for instance. Fortunately, we do not have to learn this language (Binary language). Programmers created languages which are much simpler than binary language. Here you could check *the number of programming languages*.

All programming languages have the same goal, that is being able to easily and efficiently communicate with the computer compare to binary language.

Here, is how it works :

1. You write the instructions to be executed by the computer in a programming language (e.g C++)
2. The instructions are translated in binary (0 and 1), the language understood by the computer.
3. The computer can now decode the message and executes your request.

Figure 1: Compliling Process.

## 1.2 C++ against other programming languages

Before we start talking about why C++ represents a powerful language despite its age. let's discuss the the key points to analyze before diving into a language.

There exists numerous programming languages as mentioned in above section, although some languages are interesting, they are seldom used. The main challenge that comes with these languages, is that they do not have a very big community so imagine you working on a project and you are facing a problem, it is difficult to find help since not so many people are using the the language. This explains why C++ represents a good choice for debutant programmers. You are not alone, a lot ressources are available to guide through your learning process, also C++ is still being widely used.

Another interesting aspect to look at as well is the programming language level. There are of two (02) types: **high level** and **low level**.

**high level:** is a language that is that is far from binary language and really to humans language, it allows to easily understand and translate instructions contrary to **low level** which a language closed to machine language and generally requires much more effort but gives you more control over what you can do, it is a trade-off.

C++ is a low level language. Do not panic, although coding in C++ might be a little complex, you will have in your possession a very **powerful** and particulary **fast** language. Infact, if most games are

Figure 2: Programming Language by level.

developed in C++, it is because it is the language capable of coupling speed and power, that makes it an essential language.

### 1.3 Summary of C++

Here we are going to showcase some aspects of C++ that make it an important language regardless of how long it has been since its creation.

- **Popularity** : C++ is one of the most popular languages in the world. It is used by some 4.4 million developers worldwide
- **Large Community** : There is a large online community of C++ users and experts that is particularly helpful in case any support is required. There is a lot of resources available on the internet regarding C++.
- **Portable** : Programs developed in C++ can be moved from one platform to another. This is one of the main reasons that applications requiring multi-platform or multi-device development often use C++.

- **Speed** : Programs written in C++ language execute more faster compare to most programming languages

**Snippet of C++** To give you an idea of how the code looks, let's look at a simple C++ program displaying "Hello world!" on the screen. Do not try to understand the code just appreciate the beauty and structure. We will go into details in the following sections

```

1 //=====
2 // Sample example of C++ programming language
3 //=====
4
5 #include <iostream>
6
7 using namespace std;
8
9 int main()
10 {
11     cout << "Hello world!" << endl;
12     return 0;
13 }
14 //=====

```

Listing 1: Sample example of C++ programming language

*If you are interested in knowing the story of C++ starting from its creation, you can learn all about C++ from wikipedia*

## 1.4 Summary

- Programs allow us to efficiently control actions on the computer: web browsing, text editing etc
- In order to create a program, we write instructions for the computer using a programming; source code
- The source code must be converted in binary by what we could a compiler, it allows the execution of the code.
- C++ is a widely used programming language, it is an evolution of C programming due to the fact that it allows Object Oriented Programming (OOP), a very powerful programming feature.

## 2 Environment setup

In this section, we are going to introduce the tools needed to follow this tutorial. From our previous discuss, you already know by now an important tool needed, Yes you are right, you need a Compiler, the program that converts your C++ code into the computer readable format.

Aside these, there are additional tools needed for you to code with ease

- **A text editor:** It will allow you to write your source code. On windows we have Notepad or Vi on linux. But of course, it is less recommended because as your code gets bigger and bigger, you might not be able to fully control it.
- **A compiler:** as mentioned above, it converts your source code into binary format for the computer
- **A debugger:** it helps you find bugs in your programs.

From now on we have two options (02) either we get the programs separately which is of course much complicated, but on Linux most programmers prefer to use them in that way, I will not go into much details here, instead we are going to explore the simple way. We can get a program "3 in 1", Yes you heard me correctly, a tool capable of handling the 3 listed tools. It is commonly referred to as an **IDE** (Integrated Development Environment). There are of numerous types. In this tutorial we are not going to discuss their similarities. I personally recommend Visual Studio Code and here is how you can get started with C++ for Visual Studio Code. So go ahead and install the necessary packages.

## 3 Your first C++ code

The "Hello World" program is the first but most vital step towards learning any programming language and it is certainly the simplest program you will learn with each programming language. All you need to do is display the message "Hello World" on the output screen.

```
2 // Your First C++ Program
4 #include <iostream>
6 int main() {
8     std::cout << "Hello World!";
    return 0;
}
```

Listing 2: First C++ code

**Output:**

```
|| Hello world!
```

Listing 3: First C++ code Output

1. `// Your first C++ program`

In C++, any line starting with `//` is a comment. Comments are intended for the person reading the code to better understand the functionality of the program. It is completely ignored by the C++ compiler.

2. `#include <iostream>`

The `#include` is a preprocessor directive used to include files in our program. The above code is including the contents of the `iostream` file.

3. `int main() {...}`

A valid C++ program must have the `main()` function. The curly braces indicate the start and the end of the function.

The execution of code begins from this function.

4. `std::cout << "Hello World!";`

`std::cout` prints the content inside the quotation marks. It must be followed by '<<' followed by the format string. In our example, "Hello World!" is the format string.

**Note:** `;` is used to indicate the end of a statement.

5. `return 0;`

The `return 0;` statement is the "Exit status" of the program. In simple terms, the program ends with this statement.

As you might have noticed, the code in 1 looks a little different from the one in 2 but produce the same output do not worry we are going to get to the difference soon.

In 1, line 7 we used `using namespace std;` to tell the compiler to use standard namespace. Namespace collects identifiers used for class, object and variables. Name space can be used by two ways in a program, either by the use of using statement at the beginning, like we did in above mentioned program or by using name of namespace as prefix before the identifier with scope resolution (`::`) operator. Thus with namespace `std`, `std::cout << "Hello World!";` becomes `cout << "Hello World!";` like in our previous example, much simpler right !! it is totally up to you, to define on which style suits you the most. also, the keyword `endl` is used to denote the end of a line therefore, the next line of code will be printed on a new line.

It is also important to notice that you could combine instructions into a single one. for example,

```
1 int main () {cout << "This my first C++ program, in one line.";cout <<"C++
  is fun"}
```

Listing 4: Compress C++ code

This code output the two (02) instructions on 02 lines, you can run the code and see the output.

### 3.1 Make your code more readable

In order to allow others and yourself to understand your code, it is recommended to add comments to your code. Now we are going to learn how to comment our program. We introduced the concept of the in the previous section but lets dive deeper into it.

There exists two (02) types of comments :

- **Short comments:** as stated in the names they are short and can be written in one line of code. To write a short comment, you just need to start with `//` following by your comment.

```
1 // This is my first comment.
```

Listing 5: First short comment

- **Long comments:** if your comments are long enough and can not fit in one line, you can have a block comment. You just need to start and end your block comment with `/*`.

```
1 /* The following code is a little more complexe thus I will take my time
2    and explain every single line of code, because a week from now I may
3    not have forgotten.
   */
```

Listing 6: First short comment

Generally, we do not write too much in the comment section, just the necessary information, unless you have to.

- **Let's comment our code**

```

2 //=====
// Sample example of C++ programming language
//=====
4
#include <iostream> // include the iostream library
6
using namespace std;
8
/*
10 The role of the "main"
The main function gets called when the program is started
12 */
14
int main()
16 {
    cout << "Hello world!" << endl; // Prints the message
18     return 0; // Ends the program
20 }
//=====

```

Listing 7: Comments in C++

After you run this code, nothing will change, the output will still be the same because comments are simply ignored by the compiler.

### 3.2 Summary

- The execution of code begins from the `main()` function. This function is mandatory. This is a valid C++ program that does nothing.
- The `cout` is used to display a message.
- You can comment your codes in two (02) ways `// Comment` or `/* Comment */`
